

Space Exploration Technologies (NASDAQ: SPCX), better known as SpaceX, had a successful IPO launch. The stock popped 19% on its debut and has continued to trade even higher since. Even with SpaceX stock trading substantially above its IPO price as of this writing, many see potential catalysts for it to keep climbing over the long run. It claims to have the largest addressable market in history, thanks in large part to the growing demand for enterprise artificial intelligence (AI) infrastructure and its unique ability to serve that market. CEO Elon Musk even suggested SpaceX's revenue could hit \$1 trillion by 2030 in a since-deleted post on X. So, should you buy the stock even after its strong debut? History provides a clear answer.

SpaceX is unlike any IPO in history. It garnered a massive valuation of \$1.77 trillion at its IPO price and raised about \$85.7 billion in its offering after underwriters exercised their option to buy more shares. Both are records. Still, it may be helpful to look at the track record of IPOs in general and of those more similar to SpaceX over the last 65 years.

Professor Jay Ritter has collected data on U.S. IPOs since 1960. The average first-day return is 17.7% through 2025. To that end, SpaceX's 19% first-day return is right in line with the average, although slightly below the average of IPOs since 2010 (22%). However, the average IPO doesn't fare so well in the long run after that first-day pop. Since 1980, the average one-year return for IPO stocks has been just 5.6%, well below the S&P 500's (SNPINDEX: ^GSPC) average return.

That number has fallen into negative territory in recent years. The average one-year returns for IPOs in 2021 through 2024 ranged from -11.6% to -49.1%. The average since 2011 is -1.7%. While some volatility is expected in the first year of an IPO, they've still struggled to outperform the market on average within the first three years following their debut. Total returns for IPOs since 1980 over their first three years of trading trail the market by 20.5 percentage points.

Tech companies tend to fare better than non-tech companies, though. The average three-year buy-and-hold return from their first closing price for tech stocks since 1980 only trails the market by 12.7 percentage points. If you look at tech IPOs with more than \$100 million in sales and exclude companies that went public at the height of the dot-com bubble, you finally get some good news. Those issues produced average three-year returns of 53.1% from their first close, beating the market average by 13.7%. For reference, though, SpaceX stock is already up nearly 30% from its first-day close as of this writing, so there's still not that much upside left based on historical averages.
